Building in Harmony with Nature

An ecological concept for surface area reinforcement

- High load bearing capacity through load distribution
- Near-natural decentralised drainage system
- Maintains the living soil layer
- Treatment of polluted precipitation runoffs
- Groundwater protection and new creation

www.tte.eu
HÜBNER-LEE: 20 years of Tradition and Innovation

TTE®: A surface area reinforcement concept to protect the environment

The goal of the company founders Ernst and Gyung Hyun Hübner since starting the company in 1991 has always been to exactly assess the needs of its customers and to offer both practical and economic solutions to satisfy these. HÜBNER-LEE has proven its innovative and inventive competence based on the numerous patent and registered design applications it has made. These own developments for various areas of use were continuously optimised and successfully tested by officially recognised institutions. In this way the trading house was transmuted into a manufacturer of innovative solutions for ecological ground fortification.

The TTE® system developed by the HÜBNER-LEE company has prevailed in the horse branch as an internationally recognised top concept for riding arenas and exercise areas. The TTE® riding arenas are designated as a “dance floor for horses”.

Through use of the TTE® system also outside facilities such as parking spaces covered in vegetation and paved surfaces take on real ecological functions. In contrast to sealed surfaces TTE® areas drain off any rain directly on the surface and reduce the load on local drains. This not only applies for the areas covered in vegetation but also for TTE® paved surfaces. Cleaning of the surface water takes place through the humus layer which is kept intact and covered by the TTE®. Other “ecological coverings with a base layer” cannot achieve this because of their construction.

Floods and climate change show clearly how it is urgently necessary to have ecologically built up areas and that there must be a rethinking process in the direction of “Retention of drainage surfaces with a living ground zone”. There are over 5,100 references now available for TTE® ground reinforcement on 2,500,000 m² in Europe (status at 31.12.2012). These daily deliver evidence for the high functional reliability of the TTE® system.

One further product area concerns the products which have proven themselves for years now made from recycled plastic for market gardens such as the flexible CC pathway plates and various mobile plate systems. There are currently about 5,000 tons of recycled plastic marketed annually, products from injection moulding, casting, pressing and deep drawing systems - Made in Germany.

HÜBNER-LEE customers are actively supported right from the planning through to the building phase by a competent advisory service. It is particularly in the area of development of individual problem solutions that customers value the practical approach and the amazingly simple realisation of previously cost-intensive projects.

Dear customers and business friends!
The “skin of the earth“ - the ecological system, the soil – is comparable with that of people. About 3 kg of micro-organisms live in and on our body while in which the uppermost layer of the earth there are up to 200 million micro- and macro-organisms per m². There is no life without these. We will die if all of the pores in our skin block up and there no exchange possible of moisture and also no breathing is possible. In the same way we are “asphyxiating“ our nature through compaction and sealing. Important functions such as breathing, filtering and cleaning of the water to be drained off as well as creation of new groundwater fail. Nature is being ever more destroyed through such interventions and a putative “compensation“ must be created.

The solution for the intervention-compensation problem: simply do not intervene. The lawmaker demands environmental protection, but who is acting? Be exemplary and select a building technology which integrates in nature. This can be realised economically and simply using TTE®. For the love of the environment.

Sustainable protection of vital soil functions

Supplementary extra booklets:
- A planning aid for planning, laying and maintaining water permeable TTE® surface area reinforcements
- Attestations and test certificates from test reports and scientific investigations of the TTE® system

Gyung-Hyun Hübner-Lee & Ernst Hübner
Managing Directors
TTE® elements are environmentally friendly
Demonstrably neutral for the environment

Checking and testing performed by the "Ostthüringer Materialprüfgesellschaft für Textil und Kunststoffe GmbH" demonstrated that the TTE® products are neutral for the environment. The extensive tests include testing for heavy metals as well as biological aspects, for example effects on small and micro-organisms.

CO₂ reduction during production
The TTE® product is manufactured using recycled mixed plastics (Duales System Deutschland AG). Its binds CO₂ from the waste substances. 1 kg of mixed plastic stores the equivalent of about 1.5 kg of CO₂ through combustion. This means that about 7,500 tons of CO₂ are bound annually for an annual production of 5,000 tons of mixed plastic.

Also manufacture using recycled material requires less energy than when using new plastic. This represents another 1.5 kg reduction or so in CO₂ per kg of recycled plastic. CO₂ can be stored for an indefinite period of time since TTE® has a long service life and is fully recyclable.

CO₂ reduction during using/laying the product
It is usually possible to avoid any excavation work and removal from the site plus dumping of soil materials in order to create a load carrying substructure. The existing top soil can be used so there are no shipping costs incurred. There is also a strong reduction in installation and transport of mineral materials. The resource-conserving construction principle saves a great deal of fuel and therefore lowers pollution of the environment with CO₂.

Overall the reduction in building work required results in an 80% reduction in CO₂ emissions compared to conventional building methods.

Every TTE® element prevents about 12 kg of CO₂ emissions due to the non-combustion process pioneered by Duale System Deutschland AG.

The protected resource water and the earth
The TTE® system protects and keeps the top soil intact and thus also cleans water draining into the ground instead of just filtering it.

The ground, "the skin of the earth", continues to fulfil its life-giving functions for mankind and the environment. It fulfils vital ecological and economic functions as a habitat, water regulator, producer of foods and supplier of raw materials. This basis for our life is being destroyed day after day.

Just in Germany, according to data from the Bundesamtes für Naturschutz, there are about 90 hectares of land lost every day through sealing of the ground for the purposes of building roads and housing development. This represents the size of 150 football fields!

Sealed areas of ground can no longer fulfil the tasks which are so vital for us such as water storage, creation of new groundwater and water evaporation. A lack of seepage options is one of the main reasons for flooding by high floods.

Using the TTE® system the ground is neither sealed nor compacted. The valuable biological functions of the top soil, in particular for the water balance, filtering and degradation of pollutants, are protected and kept intact.

Use of the TTE® system does not represent a negative intervention since the performance and functionality of the ecosystem and the landscape are not strongly impaired. Negative interventions can be strongly minimised or compensated for through surface drainage (§ 14 of the Federal Nature Conservation Act (BNAatschG).

Why do micro- and macro-organisms mainly live in the uppermost 30 cm of the soil?
They need:
- Air
- Water
- Light (sunlight)
- Nutrition (humus etc.)
TTE®: The Load Distribution System

Retention of soil with its important ecological functions

TTE® is a drainage active surface area reinforcement system made out of solid plastic elements for greened and paved usable areas and primarily quiet and calmed traffic. TTE® is not only a covering but actually represents a revolutionary concept which creates the highest ecological value and which is very energy and resource saving. Nature is integrated in and used based on a very low construction intervention. TTE® sets new standards for ecological surface area reinforcement.

Load distributing

The patented idea of the TTE® construction element is to replace the base layer material by an intelligent load distribution and, in this way, to combine the covering and base layer into one system.

Due to a robust qualities the individual elements achieve a high deformation and pressure stability. The interlocking of the large TTE® elements achieves load distribution over an area and thus provides stabilisation and reinforcement for the substrate.

The tolerable contact pressure for the ground is therefore not exceeded through the loading from vehicle traffic. It is possible to save on the use of mineral base layer material; it can sometimes be dispensed with completely.

Innovative construction

The conventional construction principle compared to the load distribution function of TTE® system.

Ecology and Function

Achieving a near natural soil and water balance

Permanently water-permeable

- low levels of compaction secure long-term seepage capability
- a high ability to channel off water and retention of the soil allows full drainage while maintaining high retention of the rain water at the same time

Low levels of compaction - a large pore volume

- decentralised seepage both over the surface and according to the French drain infiltration principle
- large water storage capacity for time-delayed seepage
- additional dewatering measures are not required (for a test report LWG, see Verifications and Test Certificates)

Near-natural rain water treatment

- the TTE® system protects the soil and the soil life
- cleaning and filtering by a living soil layer
- treatment of contaminated drained off surface water from traffic and roof surfaces
- mineral oils are degraded by micro-organisms in the soil (dripping oil trial undertaken by the LVG in Heidelberg)
- creation of and protection of new groundwater

Optimally plantable

- a highly plantable area
- protection of the turf through raised webs
- direct connection to the ground
- good root development because of low levels of compaction
- good supply of water, air and nutrients
- configuration of fortified usable areas in a near-natural manner

Requirements of the water management approving authorities:

Polluted rain water must be drained off over a living soil passage.
TTE®-MultiDrainPLUS
Profile of an ecological multitalent

There are 3 different pimpled surfaces obtainable for different requirements.

Fine network: Weight 24 g/m², Mesh size ≤ 4 mm, Roller width 3.20 m, material: PE

Web thickness:
inside about 15 mm
outside about 20 mm

Interlocking: about 15 mm

Dimensions: 800 x 400 x 60 mm

There are 3 different pimpled surfaces obtainable for different requirements.

Under side

The permanently water permeable and breathable TTE® paving allows many configuration options in a combination of covering and green surfaces.

NEW!
Now also in anthracite

The advantages of a TTE® paving area:
- shear forces on the TTE® construction element are minimised
- permanently water permeable and breathable due to a high number of joints and large pore volumes
- maintenance of the ecologically valuable soil intact
- paving areas with a biological cleaning function
- no base layer required for use of passenger cars
- can be driven over by lorries
- no uneven subsidences
- marking of flexibly designable parking places
- easy to lay
- water storage capacity for a 5 cm laying bed of about 33 l/m²

A very high number of joints guarantee 100% seepage of rain water and breathability of the ground.

Paving stones can be obtained in 3 colours: grey, ruby red and anthracite

Weight: 610 g/piece.

Material: strengthened, break-resistant concrete

Dimensions: 74 x 74 x 48 mm

Commercial paved surface, can be driven over by lorries (DE)

The combination solution: TTE® paving surface with TTE® grassed covered parking places

Passenger car parking spaces, Sportwelt Rosbach (DE)
Further advantages of the TTE® construction principle

Ecological and economic in every detail

TTE® is an environmentally friendly and sustainable reinforcement solution for traffic calmed areas and usable and auxiliary surfaces:

- No uneven subsidences/unevennesses possible:
- The 4-sided, massive, interlockable TTE® interconnection only allows a minimal difference in height to neighbouring plates for:
- Very high shear strength against forces produced during acceleration, braking and turning of a vehicle steering wheel:
- Rapid and simple laying:
- Permanent greenery, also for intensive use (protection of the turf)
- A permanently even surface:
- Large pore volumes
- Low compaction
- High resistance to UV
- Permanent permeability is assured
- Very resistant to UV radiation processes
- Influence of the weather
- Even subsidences/stumbling blocks possible
- A permanently even surface:
- Even subsidences/stumbling blocks possible:
- No uneven subsidences/unevennesses possible:
- Very high shear strength against forces produced during acceleration, braking and turning of a vehicle steering wheel
- Permanent greenery, also for intensive use (protection of the turf)
- A higher amount of greenery possible (coverage of the surface of up to about 90%)
- Improved root development (no breakage of the capillaries)
- Ideal root protection for trees (report from Ing.-Büro Ökoplan, Kösching)

Options for making savings:

- Up to 80% lower material and building costs => about 10-15 EUR/m² cheaper
- Additional costs for drains and dewatering equipment usually do not arise
- Soil sealing taxes and rain water fees can be avoided completely: the top rated split sewage fees on sealed surfaces in 2012 is found in Berlin at 1.90 EUR/m² per annum.

A long service life while in permanent use; the TTE® system has been certified to have good UV stability.

The massive interlocking ensures optimal pressure distribution, avoids stumbling blocks and serves as a buffer for expansion of the material.

Development of the evenness of tested surface reinforcements over time which shows the maximum deviation as actual dimensions within 3 measurement paths on one area of the plot (2.5 m x 5.5 m).

(Source: Veithshöchheimer report 115 (2008), Opportunities and risks associated with grass covered parking spaces, Jürgen Eppele)
Drainage without a drain connection point

TTE® is both a reinforcement and a surface infiltration system.

100% seepage

In a report from LWG (Veitshöchheimer Report 115 (2008), entitled “Opportunities and and risks associated with grass covered parking spaces”, Jürgen Eppel), the runoff coefficients for the TTE® system and five other coverings capable of allowing seepage were measured. Irrigations were performed periodically for taking measurements (twice a year) which were well in excess of the 100 year repeating rainfall for Veitshöchheim (r15=600 l/s x ha = 54 l/m² in 15 minutes).

It was already possible for the TTE® construction principle 1 (greened) to demonstrate no relevant flowing off from the surface (theoretical runoff coefficient C=0). Experiences gained in practice and references obtained over 16 years confirm the permanent permeability of the system.

Further measurements verify a high drainage performance, even where there is poor permeability of the building ground as well as a good infiltration rate of the covering and bedding layer (see also investigation report from LWG, please see Attestations and Test Certificates).

The highest possible rainfall intensity for the whole of Germany (location: 83224 Grassau)*

- for property drainage (according to DIN 1986-100)*: r5, a=5; rN=472.6 l/s x ha ≤ 14.2 l/m² in 5 min
- r5, a=20; rN=670.0 l/s x ha ≤ 20.1 l/m² in 5 min
- for verification against flooding (according to DIN 1986-100)*: r15, a=30; rN=398.8 l/s x ha ≤ 35.9 l/m² in 15 min
- (for more than 800 m² of runoff-area)
- the strongest 5-minute rain event in 100 years*: r5, a=100; rN=899.3 l/s x ha ≤ 27.0 l/m² in 5 min

All TTE® construction principles fulfill the requirements of property drainage for the whole of Germany many times over. Also the verification against flooding is provided by all TTE® construction principles (except the TTE® construction principle Paving 1). It will even manage the largest possible 100 year rain event for Germany. Therefore the seepage potential (of the TTE® construction principles 2 and 3) offers reserves for the introduction of surface water to neighbouring sealed surfaces or roof areas.

*) works with the German Weather Service, Hydrometeorology Department

The water absorption capacity without taking account of any time-delayed seepage in the substrate (measured and checked by LWG Veitshöchheim)

¹) to determine an accepted value based on measured values from the LWG (dependent on the material mixture used).
²) calculated values

The dewatering of the TTE® construction principle is comparable, due to its low compaction, apart from a surface formation, with that of an infiltration ditch. A permanently high drainage performance without any run off from the surface and a large water storage capacity are achieved.

A practical test proves: 70 litres of water seep away in less than one minute on an area of about 6 m²
Near-natural decentralised storage and seepage as well as pretreatment of polluted precipitation runoffs with TTE®

TTE® as a Decentralised Infiltration System

with a natural cleaning function

Decentralised surface drainage and French drain infiltration

The TTE® construction principle favours very thin webs. The TTE® construction principle is dimensioned based on the dimensioning of infiltration ditches according to DWA-A 138. The combination of the advantages of surface area reinforcement and infiltration ditch drainage provides one with a high performance drainage system with many advantages:

- a very economic concept for decentralised rainwater storage and drainage
- a dewatering system that can be driven over directly, no loss of land area as is the case with conventional seepage constructions
- pretreatment of polluted precipitation runoffs by means of living soil passages
- at the same time the (vegetation) base layer creates a surface infiltration ditch with a huge storage capacity for dewatering sealed surfaces and roof surfaces

Treatment of polluted precipitation runoffs

According to the TTE® construction principle used the living top soil is laid over or improved with ballast auxiliary materials and soil additives. While taking account of the requirements on the soil passages according to DWA-A 138 it can be dimensioned based on the dimensioning of infiltration ditches according to DWA-A 138. The combination of the advantages of surface area reinforcement and infiltration ditch drainage provides one with a high performance drainage system with many advantages:

- a very economic concept for decentralised rainwater storage and drainage
- a dewatering system which can be driven over directly, no loss of land area as is the case with conventional seepage constructions
- pretreatment of polluted precipitation runoffs by means of living soil passages
- at the same time the (vegetation) base layer creates a surface infiltration ditch with a huge storage capacity for dewatering sealed surfaces and roof surfaces

Detailed information about the requirements upon as well as about planning and dimensioning of the TTE® dewatering system can be found in the planning aid. 1) The Deutsche Vereinigung für Wasserwirtschaft, Abwasser und Abfall e. V. (DWA) - Worksheet 138 “Planning, building and operation of systems for seeping away of rainwater” 2) DWA fact sheet 153 “Recommendations concerning handling rainwater”

Load Distribution Comparison between RStO* Construction Class V/VI and TTE® Paving 2

RSIO* Paving Construction Principle of Construction Class V/VI

Construction of parking areas and service roads on grounds which are sensitive to frost. The load carrying capacity is achieved through compaction of mineral materials. The affecting force is degraded over a supporting grains framework conically at about a 45° angle.

Results of trials undertaken according to RStO:
The distance between the curves of the applied pressure and the incoming pressure illustrates the high percentage of load distribution of about 76%. The tension on the planum is strongly reduced.

Summary:
A good distribution of the compressive stresses can be achieved through use of standardised base layer material with a defined grain-size distribution. However, this is only possible using a strong compaction power, large layer thicknesses, mostly irreversible intervention in the ecosystem and loss of the ecological function of the ground.

TTE® Construction Principle of Paving 2

For movement of passenger cars and occasional heavy goods traffic over grounds which are sensitive to frost.

Our plastic elements guarantee a high load distribution through their own load-bearing capacity, stability against deformation and extensive interconnection. This allows enormous savings in material and lower compaction of the substrate.

Results of trials undertaken with TTE®:
The curve form for the TTE® test surface is almost identical to that obtained using the RStO paving construction principle. At is also about 76%, the load distribution is at the same good level as for Construction Class V/VI according to RStO.

Summary:
The results of the trials shown that the TTE® system delivers the same performance and function concerning load distribution and fitness for purpose with a roughly 65% smaller base layer. It also, at the same time, protects the ecosystem and maintains the ecological ground function intact.

Please see extra booklet “Verifications and Test Certificates” for a detailed description and verifications
Load Distribution Comparison between FLL* SR2 and TTE® Green 2

FLL* Gravel Lawns SR2
Surfaces used for passenger car traffic with low levels of lorry and bus traffic on grounds which are sensitive to frost.
The load distribution behaviours are similar to that of the paving construction. However, the load distribution angle is steeper due to lower compaction, substrate components and a lack of a surface layer.

Results of trials undertaken for FLL:
The curve form for the load cell almost matches the curve for the loading effect. Therefore, despite higher $E_v$ values, one can only achieve a load distribution effect of about 28%.

Summary:
The gravel lawn can be considered to be “the ecological surface area reinforcement”. It is recognised in specialist circles but rarely used since it usually cannot fulfil the requirements regarding load bearing capacity, evenness and greenery under conditions of very frequent and long-term use.

TTE® construction principle of Green 2
For movement of passenger cars and occasionally heavy goods traffic over grounds which are sensitive frost.
The shear force resistant and load distributing TTE® elements reinforce the vegetation support layer and ensure a high ecological functionality of the surface due to a lower pressure on the substrate.

Results of trials undertaken with TTE®:
The curve form for the load cell for the same loading effect is relatively flat. The load distribution at an approximately 78% force dissipation is significantly higher that that for a gravel lawn.

Summary:
The TTE® construction principle is the “better gravel lawn”! Load bearing capacity, shear strength and evenness are also achieved for a higher loading and frequency of use over the long-term. At the same time better drainage is achieved due to the reduced pressure on the substrate and root protection as well as a higher ecological and vegetative functionality.

Please see extra booklet “Verifications and Test Certificates” for a detailed description and verifications.
Comparison with Open Construction Principles for Open Areas

Taken from “A comparison of an FLL gravel lawn surface with a TTE® greened area with respect to load distribution, ground contact pressure and compaction due to vehicle traffic” produced by the Ingenieurbüro Ralf Ziegler in Nürnberg (2011-2012)

“With the goal in mind of improving the water balance of our landscapes and avoiding the rapid flowing off of rain water from surfaces due to the use of sealed traffic area surfaces, one should strive to use the so-called “open” construction principles to produce water permeable traffic area surfaces (parking areas). In comparison to this there is the classic road building technology which produces water impermeable surfaces and high demands upon the load bearing capacity of the substrate ($E_v^{min.} \geq 45 \text{ MN/m}^2$) and the base layer ($E_v^{min.} \geq 120 \text{ MN/m}^2$).

Gravel lawns

- according to FLL guidelines for planning, laying and maintaining greenable surface area reinforcements
- dimensioning according to the loading classes (subdivided according to frequency of use and the maximum axle load)
- should be stable, always suitable for use, water permeable and of being coverable with vegetation
- a low compaction of the vegetation support layer of $D_{v,0} = 93\% - 97\%$ is prescribed
- Requirements on the building ground compared to those required for road building are reduced to $E_v^{min.} \geq 25 \text{ MN/m}^2$, and for the base layer to $45 \text{ MN/m}^2 \leq E_v^{min.} \leq 60 \text{ MN/m}^2$

The TTE® system

- an innovative approach to reinforcing permeable traffic area surfaces
- dimensioning is also according to the loading classes
- the load bearing capacity of the surface is primarily due to solid, load distributing TTE® construction elements (made out of recycled plastic)
- therefore the base layer is significantly smaller than that for gravel lawn areas
- construction elements protect the surface against deformation and ensure permanent evenness
- the requirements on the building ground can be reduced even further for most optimal conditions for water seepage and vegetation
- TTE® construction principles are already applicable for a load bearing capacity of the building ground from $E_v^{min.} \geq 10 \text{ MN/m}^2$
- therefore the base layer is significantly smaller than that for gravel lawn areas
- construction elements protect the surface against deformation and ensure permanent evenness
- the requirements on the building ground can be reduced even further for most optimal conditions for water seepage and vegetation
- TTE® construction principles are already applicable for a load bearing capacity of the building ground from $E_v^{min.} \geq 10 \text{ MN/m}^2$

Open Construction Principles according to FLL (1)

According to the levels of loading and the traffic intensity

The following pages are extracts from “Guideline for planning, laying and maintaining greenable surface area reinforcements” (2008 Edition, pages 13-15 from Forschungsgesellschaft Landschaftsentwicklung Landschaftsbau e.V.)

4.2 Loads on vegetation

Successful greening depends on a number of factors. The growth of the vegetation is impaired, in particular, or there is destruction of the vegetation by:

- The pressure loading:
  - from vehicles driving over it
  - under a stationary vehicle/tyres
- Loading from shear forces
  - a tight curve on a parking space access road
  - turning of the steering wheel while a vehicle is stationary
  - spinning wheels (when driving off carelessly)
- Shading (screening from receiving UV radiation)
- Dryness under a vehicle (screening from receiving rain fall)
- Heat under a vehicle (heat radiation from the exhaust system, catalytic converter and oil pan)

Increasing frequency and period of application of loads to vegetation lead to greater wear and damage to the vegetation and require increased efforts and costs to maintain it. Irreparable damage to the vegetation can occur, in particular during longer parking periods and constant frequency of use during the dormancy periods.
Open Construction Principles according to FLL (2)
Extracts from “Guideline for planning, laying and maintaining greenable surface area reinforcements” (2008 Edition, pages 13-15 from Forschungsgesellschaft Landschaftsentwicklung Landschaftsbau e.V.)

4.3 Operational loads

The following are to be taken into account during planning according to building criteria:

- Vehicle weight:
  - passenger cars, mobile homes, small transporters up to 3.5 t of permissible total weight
  - lorries up at axial load of 11.5 t
  - lorries up at axial load of 16 t
  - intensity of use

- Period of use, for example:
  - a few hours a day
  - half-daily
  - all day

- Frequency of use, for example:
  - seldom (1-2 times a week)
  - occasionally (3-4 times a week)
  - daily
  - the whole year round
  - periodically (for example exhibition site parking places)
  - half-yearly (for example at small lakes, leisure parks)

- seldom (for example entrances to fire stations, fairgrounds) or only on individual occasions

Frequency of use and change of vehicle within the period of use:

- low (one vehicle)
- medium (a few vehicles)
- high (many vehicles)

The type of daily frequency of use is put into relation with the annual chronological order. One can then derive the regeneration phases for the vegetation. The daily frequency of use consists of the period of parking of the individual vehicles and the number of individual vehicles together.

The Open and Ecological TTE® Construction Principles

The three TTE® construction principles are in line with the operational loads of the FLL

TTE® Construction Principle 1
exclusively for passenger car traffic

TTE® Construction Principle 2
for passenger car and occasional heavy lorry traffic

TTE® Construction Principle 3
for heavy lorry traffic
TTE® Construction Principle 1

exclusively for passenger car traffic up to a total weight of 3.5 t

Uses:
- private passenger car parking spaces
- garage entrances
- camper van parking spaces
- bicycle stand spaces
- footpaths & bike lanes
- ecological base layer for terraces and pavements with a paving covering or floor paving
- suitable for protected areas in nature and landscape conservation

Prerequisites:
- load bearing capacity of the building ground of at least $E_v \geq 10 \text{ MN/m}^2$
- water permeability of the ground: $k_f$ value at least $1.0 \times 10^{-6} \text{ m/s}$
- for greening: an intact top soil (virgin ground) present
  (if not → TTE® Construction Principle 2)
- inclines up to 10% managed without difficulty (also steeper slopes after consultation)

Special features:
- near-natural seepage, retention and cleaning of the rain water
- near-natural ground conditions and vegetation conditions
- very low building costs - ideal for do-it-yourself construction
- an economic long-term solution

Near-natural surface area reinforcement
This construction principle allows very environmentally friendly construction, the ecological function of which is comparable with that of a natural meadow. There is no intervention in the structure of the ground and the ground life and the natural water balance is not destroyed. Loads from pedestrians and passenger cars can be absorbed by the strong, load distributing behaviour of the TTE® system without a base layer.

Detailed information about the planning, laying and maintenance can be found in the planning aid.
Example Applications for TTE® Construction Principle 1

exclusively for passenger car traffic up to a total weight of 3.5 t

- Greened private entrance (NL)
- Private access road (DE)
- TTE® with a gravel backfilling, beer garden (DE)
- A sales area at a garden centre in Lübeck (DE)
- Water-bound covering with TTE®, about 7,000 m² of visitor pathways at the zoo in Münster (DE)

- Terrace covering made out of TTE® (DE)
- Terrace reinforcement with integral planted areas (NL)
- Terrace reinforcement with integral planted areas (NL)
- Water-bound covering with TTE®, about 7,000 m² of visitor pathways at the zoo in Münster (DE)

Creative diversity of the application options
**TTE® Construction Principle 2**

For movement of passenger cars and occasional heavy goods traffic

**Uses:**
- Public passenger car parking spaces (can be driven over vehicles of the entertainment services)
- Industrial workers and visitor parking spaces
- Private courtyard fortifications and access roads
- Entrances to fire stations and bypass roads with or without greening
- Rural roads
- Service roads
- Ecological base layer for paving coverings or floor paving

**Prerequisites:**
- Load bearing capacity of the building ground of \( E_v \geq 10 \text{ MN/m}^2 \)
- Water permeability of the building ground: \( k_r \geq 1 \times 10^{-6} \text{ [m/s]} \)
- Inclines up to 10% manageable without difficulty (also steeper slopes after consultation)
- For greening: low usage intensity / quiet traffic area surfaces

**Special features:**
- Ideal as open reinforcement of many usable and auxiliary surfaces
- Sustainable good for the environment (ground, air and groundwater)
- Near-natural decentralised storage and seepage of precipitation
- High cleaning capability

**Base layer thicknesses according to the frost resistance of the ground**

<table>
<thead>
<tr>
<th>Vegetation base layer:</th>
<th>Ballast base layer:</th>
</tr>
</thead>
<tbody>
<tr>
<td>F1 grounds: 20 cm</td>
<td>F1 grounds: 15 cm</td>
</tr>
<tr>
<td>(for TTE® Green 2)</td>
<td>(for TTE® Paving 2)</td>
</tr>
<tr>
<td>F2/F3 grounds: 25 cm</td>
<td>F2/F3 grounds: 20 cm</td>
</tr>
</tbody>
</table>

**Creation of the vegetation base layer on-site**

1. Level the top soil
2. Apply about 60% ballast (for example 2 - 32 mm)
3. Mill in about 40% of the top soil present
4. Level and compact \( E_v \geq 20 \text{ MN/m}^2 \)

**Mineral or cleaning-active base layer?**

If the seepage can be promoted over a living soil layer, one can also use the vegetation base layer for TTE® paving areas as a “cleaning-active base layer”. For the love of the environment.

Detailed information about the planning, laying and maintenance can be found in the planning aid.
Example Applications for TTE® Construction Principle 2

For movement of passenger cars and low heavy goods traffic corresponds to RStO 01 BKL V/M or RStO 12 Bk 0.3

- More than 22,000 m² of parking spaces shortly after the completion at a large shopping center near Vienna (AT)
- Visitor’s parking place for Media Markt (NL)
- Outside facility for residential building (FR)

Parking space and footpaths design with high ecological benefits

- Parking place and footpath incl. subsurface irrigation in Baku (AZ)
- Parking place for a school (FR)
- Passenger car parking (NL)
**TTE® Construction Principle 3**

**for heavy goods traffic up to 40 t**

**Uses:**
- industrial warehouse spaces and entrances
- lorry and bus parking places
- service pathways at motorway service stations
- ecological base layers for traffic area surfaces with a surface layer made out of a paving coverings or floor paving

**Prerequisites:**
- load bearing capacity of the building ground of $E_{v2}$ of at least 10 MN/m²
- inclines up to 10% manageable without difficulty (consultation is necessary for steeper slopes)
- water permeability of the building ground: $k_f$ value of at least $1,0 \times 10^{-6}$ [m/s]
- for greening: low usage intensity / quiet traffic area surfaces

**Special features:**
- a high shear strength through use of TTE® paving stones
- ecological long-term functions of the surfaces despite the lorry traffic
- surface infiltration ditch - storage of additional flowing off from the surfaces
- pretreatment of polluted precipitation runoffs

**Base layer thicknesses according to the frost resistance of the ground**

- Vegetation base layer: 20 cm
- Ballast base layer: for F1 grounds: 10 cm, for F2/F3 grounds: 15 cm

**Creation of the vegetation base layer on-site**

<table>
<thead>
<tr>
<th>Top soil present</th>
<th>Base layer present</th>

</tbody>
</table>

**Ballast base layer: for F1 grounds: 25 cm**
- for F2/F3 grounds: 30 cm

**Top soil present:**
- Mineral or cleaning-active base layer?

The ballast base layer of the TTE® Paving 3 structure can, on ecological grounds, be replaced by the base course from TTE® Green 3. The living soil layer achieves cleaning of surface water and generally increases the ecological value of the surface.

**Detailed information about the planning, laying and maintenance can be found in the planning aid**

**For high loads up to a total weight of 40 t**

**TTE® Green 3**
- $E_{v2}$ value (MN/m²) min.
- 30

**TTE® Paving 3**
- $E_{v2}$ value (MN/m²) min.
- 30

**Mineral or cleaning-active base layer?**
Example Applications for TTE® Construction Principle 3
for passenger car and increased heavy goods traffic up to 40 t

for sustainable building

Local street and courtyard fortification (FR)

Bus stop in St. Martin im Innkreis (AT)

The ecological functions are sustainably achieved despite the heavy goods traffic

Passenger car parking place (FR)

Local street (FR)

Agricultural road (DE)

Emergency stop bay (BE)

Commercially used courtyard fortification (FR)

Local street and courtyard fortification (FR)

 corresponds to RSiO 01 Bkl III/IV or RSiO 12 Bk 1.8

---

<sup>1</sup> $MN/m² = MPa$ (the unit MPa should be used outside Germany and then according to RStO 12)

<sup>2</sup> frost-resistant grounds e.g. sandy ground

<sup>3</sup> frost-sensitive grounds e.g. loamy ground

<sup>4</sup> Vegetation base layer: 60% 2 - 32 ballast or 0 - 32 mm, 40% top soil ground group 2 or 4 according to DIN 18915

<sup>5</sup> Alternatively, the supporting structure of the respective green construction can be used

<sup>6</sup> Alternatively, for a higher ecological functionality, the supporting structure of the respective green construction can be used

<sup>7</sup> Alternate filling of the TTE® construction elements with TTE® paving stones and substrata in chequerboard design
Ballast and Gravel Surfaces with TTE®

Even, hardwearing and loadable

Uses: for pedestrians, passenger car and heavy lorry traffic
- maintenance free and loadable reinforcements made out of coarse pore ballast/gravel or sand
- courtyard areas and warehouse areas, ways and entrances, parking spaces, agricultural roads etc.

Special features:
- secures the evenness of the surface layer: no settlements (potholes or ruts)
- a pleasant accessible and hardwearing reinforcement made out of loose bulk materials
- many design options and a natural appearance
- a permanently high drainage performance
- cost-effective reinforcement
- separation of the covering and base layer

TTE® with mineral filling + TTE® paving combination (for example TTE® construction principle 2)

Supporting structure for paving coverings or floor paving

TTE® as an ecological base layer allows permanent seepage

Uses: for passenger car and heavy lorry traffic
- ecological base layer for paving coverings or floor pavings
- particularly suitable for inhomogeneous and low bearing capacity building ground
- building over the root areas of trees

Prerequisites:
- load bearing capacity of the building ground of $E_2$ of at least 10 MN/m²
- water permeability of the building ground: $k_f$ value of at least $1,0 \times 10^{-6}$ [m/s]

Special features:
- a higher ecological value, permanent and better dewatering performance
- as a conventional "eco-paving constructional principle"
- secures evenness of the surface: no subsidence/setting of the surface layer is possible, no placements of the paving stones at an incline
- optimal vegetative conditions for greenable paving covers for laying as a TTE®-Green construction principle

Details for planning and laying of mineral as well as water-bound surface layers can be found in the planning aid
Hard Shoulder Reinforcements

Edge reinforcement of road areas

**Uses:**
- reinforcement of the road hard shoulder

**Special features:**
- permanently even road edge reinforcement
- a simple solution for improving the road safety
- protection against ruts and damage in the hard shoulder
- warning for driving over by means of an acoustic signal and vibration
- visible delimitation of the driving lane area (marking by coloured TTE® paving stones)

Surface Infiltration Ditch

The combination of the surface area reinforcement and infiltration ditch

**Uses:**
- near-natural decentralised storage and seepage of precipitation
- a surface dewatering system which can be driven over (up to 40 t)
- discharge of surface water from sealed surfaces/roof areas

**Prerequisites:**
- load bearing capacity of the building ground of $E_{d}$ of at least 10 MN/m²
- water permeability of the building ground: $k_f$ value of at least $1,0 \times 10^{-6}$ [m/s]

**Special features:**
- storage of large quantities of rain water with additional dewatering equipment and drain connection point
- treatment of polluted outflows over an approximately 25 - 30 cm thick living soil layer
- due to the high, widespread cleaning function of greened and paved TTE® surfaces, also usable for greater pollution of the rain water

---

Root Protection for Tree Plantations with TTE®
Optimal protection for the root zone through load distribution

Uses:
- Root protection
  - reinforcement and protection of existing root areas
  - root protection in pedestrian and traffic areas

Special features:
- the strong load distribution and low compaction of the TTE® construction principle allow overbuilding of root areas
- unlimited root zone and free root growth, through connection to natural ground
- optimal ground conditions like breathability and water supply
- plantable or with a paved covering (continuous through to the stem area)
- replaces costly tree disks

Footpaths and Jogging Paths with TTE®
Easy on the joints due to an elastic layer

Uses:
- for passenger car traffic and care vehicles
  - footpaths & bike lane areas
  - jogging and walking paths, exercise tracks

Prerequisites:
- load bearing capacity of the building ground of $E_D$ of at least 10 MN/m²
- water permeability of the building ground: $k_f$ value at least $1.0 \times 10^{-6}$ [m/s]

Special features:
- the interlocking and load distribution of the TTE® elements allow overbuilding of an elastic layer
- a very pleasant and easy on the joints accessibility
- can be used in any weather

TTE® construction for root protection (for example for TTE® construction principle 2)

E$_D$ value (MN/m²) min.

Footpaths and Jogging Paths with TTE®
Easy on the joints due to an elastic layer

Uses:
- for passenger car traffic and care vehicles
  - footpaths & bike lane areas
  - jogging and walking paths, exercise tracks

Prerequisites:
- load bearing capacity of the building ground of $E_D$ of at least 10 MN/m²
- water permeability of the building ground: $k_f$ value at least $1.0 \times 10^{-6}$ [m/s]

Special features:
- the interlocking and load distribution of the TTE® elements allow overbuilding of an elastic layer
- a very pleasant and easy on the joints accessibility
- can be used in any weather
Football Ground with Artificial Turf and TTE®

Imitation of a natural turf through an impact dampening behaviour

Uses:
- weather-proof artificial turf ground

Prerequisites:
- load bearing capacity of the building ground of $E_2$ of at least 10 MN/m²
- water permeability of the building ground: $k_f$ value at least $1.0 \times 10^{-6}$ [m/s]

Special features:
- permanent and rapid dewatering, no stagnant water
- imitation of a natural turf through an impact dampening behaviour
- securing the permanent evenness
- usable for every weather and time of the year
- self-construction possible (for example associations)
Individual TTE® solutions

Roof greening on a house boat (NL)

Multitalent TTE®
One product - many options

Beach terrace with a bamboo overlay (NL)

TTE® with gravel backfilling, wooden superstructure and TTE® paving stones (NL)

Runway for sports aircraft (DE)

Market presence of HÜBNER-LEE products in Germany

There are over 5,100 references now available for TTE® ground fortification on 2,500,000 m² in Europe (status at 31.12.2012). These daily deliver evidence for the high functional reliability of the TTE® system.
Competence in providing advice with many years of experience

TTE® users are actively supported right from the planning through to the building phase by a competent advisory service. The area of development of individual problem solutions is where customers particularly value the practical approach and the amazingly simple realisation of previously cost-intensive projects.

We are happy to support you with our many years of experience to realise your project.
